For Review Only

Abstract

Achievement in different domains such as academics, music, or visual arts plays a central role in all modern societies. Different psychological models aim to describe and explain achievement and its development in different domains. However, there remains a need for a framework that guides empirical research within and across different domains. With the *talent development in achievement domains* (TAD) framework, we provide a general talent development framework applicable to a wide range of achievement domains. The overarching aim of this framework is to support empirical research by focusing on measurable psychological constructs and their meaning at different levels of talent development. Further, the TAD framework can be used for constructing domain-specific talent development models. With examples for the application of the TAD framework to the domains of mathematics, music, and visual arts, the review provided supports the suitability of the TAD framework for domain-specific model construction and indicates numerous research gaps and open questions that should be addressed in future research.

Keywords: talent development; achievement; giftedness; expertise; domain specificity; education

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

2

Talent Development in Achievement Domains: A Psychological Framework for Within and Cross-Domain Research

Achievement is defined both as the action of achieving something as well as the result accomplished through effort, skill, or courage in response to given conditions (“achievement,” n.d., Oxford English Dictionary). Achievement in different domains such as academics, the arts, or sports plays a central role in all modern societies. For example, students’ school achievement influences not only their current development but also exerts a life-long impact on variables related to socio-economic status (Slominski, Sameroff, Rosenblum, & Kasser, 2011) and health (Silles, 2009). From a societal perspective, professional sports like basketball or soccer have developed into multi-billion dollar markets; and professionals’ achievements in science, technology, engineering, and mathematics drive the scientific and technological development of a country and contribute to its economic well-being and competitiveness (Halpern et al., 2007).

Given the central role of achievement in modern societies, several theoretical models from different scientific psychological strands like differential, educational, or industrial and organizational psychology; giftedness research; or research on expertise aim at explaining the development of achievement in general and of high achievement in particular (for overviews, see Hambrick, Macnamara, Campitelli, Ullén, & Mosing, 2016; Sternberg, 2004; Subotnik, Olszweski-Kubilius, & Worrell, 2019; for meta-analyses, see e.g., Hattie, 2009; Ng, Eby, Sorensen, & Feldman, 2005; Schneider & Preckel, 2017)¹. People are not born as (high) achievers but eventually develop into such. From a psychological perspective, the development of achievement can be described as a process of talent development in which a person’s potential for achievement develops into actual achievement. In this regard, some central research questions include the following. What constitutes potential for achievement? Can potential be

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

3

1
2
3 measured and if yes, how? How does it develop into high achievement? Are there common
4
5 principles of talent development across achievement domains like mathematics, music, or visual
6
7 arts? How do developmental trajectories differ across domains? At what time points during the
8
9 developmental process are particular interventions helpful or even necessary?
10
11

12 The current work aims to contribute to research related to these questions by suggesting a
13
14 talent development framework that should be applicable to a wide range of achievement
15
16 domains. This framework could act as a starting point for the development of domain-specific
17
18 models, which, in turn, could be used for the description, explanation, prediction, and fostering
19
20 of high achievement and its development in these domains. Such a framework would facilitate
21
22 the synthesis of research findings from different domains and could identify generalizations
23
24 across domains (e.g., general developmental processes) and specifications for particular domains
25
26 (e.g., starting age or peaks of development). The framework could thus be extremely helpful for
27
28 an integrative discussion of how to model talent development in different domains. Overall,
29
30 such a framework could help to advance the field, which is in need of more systematic,
31
32 sustainable programs of research, more coordination among researchers, and a stronger link
33
34 between theory and practice (e.g., Dai, Swanson, & Cheng, 2011; Hambrick, Burgonye, &
35
36 Oswald, 2019; Preckel & Krampen, 2016). The current work builds on existing formulations yet
37
38 serves as a springboard for the development of a next generation framework for talent
39
40 development. Accordingly, all ideas and conceptions presented here are open to discussion and
41
42 further elaboration.
43
44

46
47
48

Fundamentals of the Talent Development in Achievement Domains (TAD) Framework

49
50 For the development of the framework, 12 researchers (i.e., the authors) from different
51
52 fields of psychological research on talent development met for a two-day summit in Munich,
53
54
55
56
57
58
59
60

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

4

Germany, to discuss talent development from multiple perspectives including music psychology, art psychology, educational psychology, differential psychology, giftedness research, research on expertise and instructional psychology. The goals for the summit included identifying (a) requirements for a talent development framework, (b) common principles for talent development across achievement domains grounded in psychological science, (c) potential gaps in extant models, and also (d) coming up with research questions that had the potential to facilitate moving the field forward. These goals were pursued in full group discussions. Melding views into a collaborative effort meant engaging with intellectual and values-based disagreements, but eventually, the group reached consensus for a collaborative statement of needed work in the field. Subsequently, these ideas were further developed within a common writing project.

Results are presented here.

First, we describe the requirements for the framework the group agreed upon. Second, as the framework builds on existing formulations—and especially on the megamodel by Subotnik, Olszewski-Kubilius, and Worrell (2011)—we summarize the model and its basic principles. Third, we outline the contributions of the TAD framework relative to the megamodel. Fourth, we describe the TAD framework in detail. Finally, to show the potential of the TAD framework for cross-domain applications, we demonstrate its application to different achievement domains like mathematics, music, and visual arts.

Requirements for the TAD Framework

Quality criteria for scientific theories include comprehensiveness, precision, testability, parsimony, empirical validity, and heuristic and applied value (Cramer, 2013). We do not claim to present a new theory of talent development, but we aim to offer a catalyst for the development of domain-specific talent development models. Therefore, these quality criteria guided the

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

5

1
2
3 formulation of requirements for the framework. We elaborate on the requirements in the
4
5 following paragraphs.
6

7
8 The framework *integrates different strands of psychological research*. An increasing
9
10 number of recent papers on achievement and talent development integrate theoretical
11
12 perspectives and empirical findings from different fields of psychology (e.g., Hambrick et al.,
13
14 2016; Lubinski, 2016; Subotnik et al., 2011; Ullén, Hambrick, & Mosing, 2016). The TAD
15
16 framework should mirror the comprehensiveness of these papers and integrate evidence for
17
18 predictors of achievement and trajectories of talent development in different domains, based on
19
20 research from different psychological fields including expertise, giftedness, or education and
21
22 instruction (i.e., an evidence-based integrative approach).
23
24

25
26 The framework *reduces complexity and is in part testable*. The focus of the framework is
27
28 on person-related psychological variables. We acknowledge the important role of environmental
29
30 and genetic factors, as well as their complex interaction with each other and with person-related
31
32 psychological variables, and we summarize main findings on the role of these factors in talent
33
34 development in the section below entitled Environmental and Genetic Factors. However, these
35
36 factors are not emphasized in the framework itself because they would make it too complex to be
37
38 ~~falsifiable~~ empirically testable. Rather, we investigate these factors on talent development as they
39
40 reflect on person-related psychological variables (e.g., reception of opportunities offered by the
41
42 environment). The focus on person-related psychological variables facilitates assessment and the
43
44 formulation of testable hypotheses deduced from the framework.
45
46
47
48

49
50 The framework *uses clear and consistent construct definitions*. To avoid using different
51
52 terms for the same constructs or the other way round and to allow for the integration of research
53
54 findings from different domains and research strands, it is of utmost importance to have common
55
56
57
58
59
60

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

6

1
2
3 definitions of central terms. We therefore offer our definitions of central terms when presenting
4
5 the TAD framework (see below).
6
7

8 The framework *offers a ranking of predictors according to their importance at different*
9 *developmental levels to predict talent development.* The focus of the framework is on person-
10 related psychological variables, which comprise a wide variety of cognitive, non-cognitive, and
11 psychosocial constructs. These constructs differ in stability and have their own developmental
12 trajectories. Further, what constitutes achievement and what is required for it varies over time
13 and developmental level (e.g., demands vary for beginners or advanced learners in a domain).
14 The framework considers this concern and formulates hypotheses for the relative importance of
15 different cognitive, non-cognitive, and psychosocial constructs in the process of talent
16 development.
17
18
19
20
21
22
23
24
25
26
27

28 The framework *integrates psychological processes and their specificity for the*
29 *development of high achievement.* The framework outlines general principles and processes of
30 talent development (e.g., learning) as well as aspects that are more specific for the development
31 of high achievement (e.g., profile formation and specialization) within specific domains or for
32 specific groups. It further integrates these processes into the overall talent development process
33 to allow the formulation of hypotheses (e.g., regarding temporal order).
34
35
36
37
38
39
40
41

42 The framework *defines potential outcomes within the process of talent development.*
43 Talent development is understood as a cumulative process in which earlier outcomes
44 (achievements) influence later outcomes (achievements). The framework defines potential
45 outcomes at various levels of talent development that, in turn, influence achievement
46 development in the future. However, the framework does not define any normative results or
47 ceiling for talent development.
48
49
50
51
52
53
54
55
56
57
58
59
60

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

7

1
2
3 The framework *informs identification, fostering, and counselling*. The general
4
5 framework, as well as the domain-specific models, should provide information about indicators
6
7 for early/middle/late outcomes of talent development. These should be specific enough to be
8
9 used for the identification of achievement potential and for tracking progress in a talent domain.
10
11 The framework further informs interventions suitable for supporting specific changes and
12
13 progress in the talent development process.
14
15

Point of Origin: The Megamodel of Talent Development

16
17
18 The megamodel (Subotnik et al., 2011) provides a synthesis of the psychological science
19
20 behind talent, giftedness, and expertise (see Figure 1 with notation below). Therefore, it was
21
22 used as the springboard for the TAD framework. Similar syntheses are also provided by other
23
24 authors (e.g., in the multifactorial gene–environment interaction model by Ullén et al., 2016).
25
26 However, the megamodel includes a developmental (long-term) perspective that is needed to
27
28 describe talent development in different achievement domains.
29
30
31

32
33 ***Figure 1 about here***
34

35 The megamodel describes the talent development process from potential to eminence² by
36
37 four successive levels: ability, competence, expertise, and eminence (Jarvin & Subotnik, 2010).
38
39 Transition between those levels is distinguished by creativity as a source of identification
40
41 (person), a creative use of knowledge (process) toward competence and expertise, and in the later
42
43 stages of talent development trajectories, the creation of new ideas and domain contributions
44
45 (product). The basic principles behind the megamodel are as follows.
46
47
48

- 49 1. *Abilities are important for high achievement, both general abilities and domain-specific*
50
51 *abilities*. Individual differences exist in both sets of abilities, yet they remain malleable and
52
53 need to be developed to achieve individual goals. The predictive validity of general and
54
55
56
57
58
59
60

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

8

1
2
3 domain-specific abilities is well established in academic domains with domain-specific
4 abilities having a strong and consistent positive effect on creative productivity (e.g.,
5 Lubinski, 2016) or in the work place for the prediction of job performance and training
6 success (Bertua, Anderson, & Salgado, 2005). However, many domains remain unexplored
7 with regard to identifying which constellation of general and domain-specific skills are
8 necessary, even if not sufficient, to allow for successful continuation in a field or domain.
9

- 10
11
12
13
14
15
16
17 2. *Each domain of ability has different beginning, peak, and end points. As a consequence of*
18 *these varying trajectories, abilities in some domains are not evident until later in a school*
19 *career, whereas others are recognizable early* (see Figure 2). The existence of varied
20 trajectories (Simonton, 1997, 2001) has implications for serving talented youth. For
21 example, some (although not all) children with potential for deep involvement in
22 mathematics can be engaged early in the school years with creative and advanced work, and
23 many careers in mathematics begin earlier than in other domains. Differences in trajectories
24 can be seen most explicitly in performers where physiological differences impede or enhance
25 functioning, such as lung power in wind instrument players and flexibility in female
26 gymnasts. A violinist entering a music conservatory at age 18 tends to be far more
27 experienced in the music world than a clarinetist, having started her trajectory at age 4 or 5
28 rather than age 12 (Subotnik, 2004). Finally, some important achievement domains require
29 human experience and understanding of human behavior, such as diplomacy or health care,
30 and thus are introduced in early adulthood.
31
32
33
34
35
36
37
38
39
40
41
42
43
44
45
46
47
48

- 49 3. *Abilities that are not deployed do not develop, and appropriate opportunities must be offered*
50 *at appropriate times.* Some of the most seminal work on the role of instruction for talent
51 development was derived from the work of Bloom and his colleagues (Bloom, 1985). Early

1
2
3 teachers and families provided occasions for playful engagement with a domain, leading to
4 falling in love with or developing a passion for the domain, whereas later teachers focused on
5 developing skills and expertise, ultimately helping the student or tutee develop a unique
6 niche or voice. The most important outcome of these explorations into elite athletes, artists,
7 and scholars was to show that what they needed in terms of opportunities and instructors or
8 coaches changes over time (for reviews on the role of instruction for academic achievement,
9 see, Hattie, 2009; Schneider & Preckel, 2017).

- 10
11
12
13
14
15
16
17
18
19
20 4. *Mental and social skills transform abilities into competencies, expertise, and creative*
21 *productivity*. They play a major role in individuals' receptiveness to opportunities. The
22 development of one's own abilities requires that a person has the confidence or motivation to
23 take advantage of opportunities or the autonomy to seek them out (e.g., Noble, Subotnik, &
24 Arnold, 1996). Mental and social skills are important for dealing with obstacles to progress
25 and pushback against creative ideas, for investing abilities, or long-term commitment (for an
26 overview on the role of psychosocial skills in K-12 education, see, Lipnevich, Preckel, &
27 Roberts, 2016).
28
29
30
31
32
33
34
35
36
37
38 5. *Finally, talent development is not limited to the school year and curriculum*. Rather, talent
39 development incorporates extra and co-curricular activities, and involves a long-term view of
40 advising talented children and youth on activities and educational institutions that will best
41 serve them in meeting their individual goals.
42
43
44
45

46
47 ***Figure 2 about here***
48

49 **The TAD Framework Relative to the Megamodel**

50
51 The TAD framework (see Figure 3) draws heavily on the megamodel. It adopted the
52 basic principles of the megamodel described in the preceding section. It describes the talent
53
54
55
56
57
58
59
60

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

10

1
2
3 development process by four successive levels (Column 1 of Figure 3: “Developmental Levels”)
4
5 and it follows the notion of a trajectory in talent development moving from general abilities to
6
7 specific skills and competencies (Column 2: “Increasing Specialization”). It conceptualizes
8
9 talent development as dependent on a multiplicity of factors whose relative importance can vary
10
11 with level of talent development (Columns 3 & 4: “Level-dependent predictors and indicators”).
12
13

14
15 ***Figure 3 about here***
16

17 However, the TAD framework provides some departures. Whereas the megamodel
18
19 emerged from a descriptive synthesis of the literature, the TAD framework goes a step further by
20
21 making talent development more suitable for empirical investigations and more usable for cross-
22
23 domain applications. Some specific characteristics of the TAD framework, which follow from
24
25 this elaboration, include the following:
26
27

- 28 • A primary psychological focus on measureable, person-related variables to reduce
29
30 complexity and to promote testability.
31
32
- 33 • A stronger focus on internal processes that lead to interest and success in a domain (e.g.,
34
35 ability differentiation, profile formation, identity formation). Particular attention is drawn to
36
37 the formation and specific role of ipsative ability-personality profiles because previous
38
39 research has shown that these profiles are highly predictive of individuals’ achievements and
40
41 domain choices (e.g., Lubinski, 2016; Wang, Eccles, & Kenny, 2013; Wang, Ye, & Degol,
42
43 2017).
44
45
- 46 • A suggestion of important predictors and indicators of talent development at different levels
47
48 of the talent development process. These predictors and indicators can be assessed
49
50 empirically and can therefore be used to identify achievement potential at various levels and
51
52 to track progress in the talent domain. Further, and in accordance with the megamodel, TAD
53
54
55
56
57
58
59
60

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

11

1
2
3 acknowledges that within the process of talent development the relative importance of
4 predictors can vary. For example, the validity of agreeableness for explaining academic
5 performance seems to decrease with educational level (Poropat, 2009). The TAD framework
6 therefore suggests prioritizing the investigation of predictive contributions to the next
7 sequential level of talent development, rather than long-term contributions toward
8 transformational achievement.
9

- 10
11
12
13
14
15
16
17 • Like the megamodel, the TAD framework should be transferable to different domains in
18 which the framework guides model development. The TAD framework offers some
19 guidelines and examples for this endeavor. For example, the framework scaffolds model
20 development by differentiating levels with their respective predictors and indicators of talent
21 development. The creation of a domain specific talent development model requires outlining
22 evidence for each part of the framework related to the respective domain, deducing evidence-
23 based applications (assessment, intervention), pointing out gaps in the literature and
24 suggesting a research agenda for specific domains. In the section, “Application of the TAD
25 Framework to Different Achievement Domains” (see below), we present examples for uses
26 of the TAD framework for model development in music, mathematics, and the visual arts.

40 TAD Framework Description

41 Developmental Levels

42
43 As depicted in Figure 3, the first column of the TAD framework provides a basic
44 orientation to lifespan development, closely paralleling aspects of the megamodel (Subotnik et
45 al., 2011). With increasing levels of talent development, the number of persons decreases
46 (Simonton, 1999), as suggested by the triangle in that column. In the following, we give
47 definitions for the levels and describe what they entail.

Aptitude refers to variations in individuals' constellations of psychological factors that are predictive of a positive development of achievement or future performance. It reflects individual differences in psychological variables (e.g., musicality, mathematical cast of mind, spatial ability) that would predispose a person to becoming interested in or engaging in activities relevant to a particular kind of achievement domain³. In some domains, these may manifest themselves very early, in others, later. However, they tend to have a quality of a *natural fit* between the person and the content or challenges of that activity. In the megamodel, the term "ability" is used for this level. However, we understand that ability refers to variations in an individual's capacity for *present* performance on a defined class of tasks (Carroll, 1993, p.16). To stress the meaning for the *development* of achievement or *future* performance, the term "aptitude" is used in the TAD framework.

Competence refers to a cluster of related and systemically developed abilities, knowledge, and skills that enable a person to act effectively in a situation and that result from systematic learning (Gagné & McPherson, 2016). Once individuals who have demonstrated some aptitude for an activity have engaged in it for a while, their performance typically improves, setting them apart from their peers. Often, this growth is accomplished under formal tutelage. Individuals acquire a variety of increasingly domain-specific skills giving them multiple options to act efficiently, and may see themselves headed toward a career in that domain.

Expertise refers to a high level of consistently superior achievement; an expert has a strong grasp of the field or domain such that he or she is capable of generating good solutions to important domain problems (Subotnik et al., 2019). This step typically involves overt commitment to a domain, with a concomitant increase in knowledge base and yet more domain-

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

13

1
2
3 specific skills, often acquired through lots of particularized education. Even with the acquisition
4
5 of considerable expertise, depending on the domain, transitioning to full-time professional status
6
7 can be difficult. Although reputation does not ensure a high level of expertise (Ericsson, 2006),
8
9 the acquisition of a full-time professional status usually requires the recognition as an expert by
10
11 others similarly engaged in the domain. Relatedly, the provision of insider knowledge is
12
13 frequently helpful, as are well-developed psychosocial skills.
14
15

16
17 *Transformational achievement* refers to levels of achievement that go beyond expertise
18
19 by generating creative responses that require breaking domain boundaries or setting new
20
21 questions. This outcome can comprise a single significant contribution or sustained
22
23 contributions that have had or will have a lasting and memorable impact on how work in the
24
25 field is conducted (Jarvin & Subotnik, 2010; Subotnik, Olszewski-Kubilius, & Worrell, 2018).
26
27 For those lucky or skilled enough to successfully navigate the socio-cultural and chance factors
28
29 that can quash hopes for a professional career in one's chosen achievement domain, one still
30
31 faces the challenge of taking experience and expertise and translating it into some kind of
32
33 tangible achievement, often of a strongly creative variety, and of sustaining that mode into later
34
35 life. Our understanding of transformational achievement resembles the description of eminence
36
37 in the megamodel. However, the term, eminence, can easily be misunderstood (for a discussion,
38
39 see, Worrell, Subotnik, & Olszewski-Kubilius, 2018). Therefore, we use the more descriptive
40
41 term, transformational achievement, within the TAD framework.
42
43
44
45
46

Increasing Specialization

47
48
49 Column 2 of Figure 3 focuses on the increasing specialization of talent across
50
51 achievement levels. People usually do not achieve at the same level in different domains. That
52
53 is, high achievement is most often domain specific because it results from intensive investment
54
55
56
57
58
59
60

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

14

1
2
3 and engagement that draws off time for investment and engagement in other activities. This
4
5 focus indicates a process of increasing specialization within talent development. Within the
6
7 TAD framework, we assume the following five principles and processes behind this
8
9 specialization process.
10
11

12 First, general and specific cognitive abilities are important during the whole process of
13
14 talent development. There is overwhelming evidence for interindividual differences in
15
16 psychological variables related to achievement in general (e.g., intelligence or conscientiousness;
17
18 Ng et al., 2005; Nisbett et al., 2012; Richardson, Abraham, & Bond, 2012; Schneider & Preckel,
19
20 2017; Strenze, 2007) as well as for high levels of achievement (Hambrick et al., 2016; Lubinski,
21
22 2016). The predictive validity of general and specific cognitive abilities is well established. In
23
24 their review of the literature on changes in the validity coefficients associated with general
25
26 cognitive ability tests due to the passage of time, Reeve and Bonaccio (2011) concluded that
27
28 “scores based on measures of *g* can predict outcomes over long periods, with only minimal (if
29
30 any) degradation in the magnitude of the criterion-related validity coefficient over time” (p. 264).
31
32 General cognitive ability remains a significant predictor of job performance even after extensive
33
34 job experience (for an overview, see Hambrick et al., 2019). In their meta-analyses, Zabolni,
35
36 Kranzler, and Gage (2018) found positive relations of general and more specific cognitive
37
38 abilities with academic achievement, with general cognitive abilities having the largest effect
39
40 across all achievement domains and ages (mean effect size of $r^2 = 0.54$). Moreover, earlier
41
42 domain-specific abilities have a strong and consistent positive effect on later creative
43
44 productivity, job performance, or training success (Bertua et al., 2005; Lubinski, 2016).
45
46
47
48
49
50

51 Second, general and specific cognitive abilities are malleable. Even general cognitive
52
53 ability that, in relative terms, is a rather stable characteristic of people shows some variation
54
55
56
57
58
59
60

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

15

1
2
3 across the life span: Around half of the individual differences in general cognitive ability are
4
5 stable across most of the human life course, but the other half are not (Deary, 2014). Lyons et al.
6
7 (2009) found that over a time span of 35 years (between age 20 and age 55), 44.6% of the
8
9 individuals had score changes of half of a standard deviation or more in a measure of general
10
11 cognitive ability. Environmental factors contribute to a comparable amount as genetic factors to
12
13 individual differences in measures of cognitive ability (Knopik, Neiderhiser, DeFries, & Plomin,
14
15 2016). A case in point is education. A recent meta-analysis by Ritchie and Tucker-Drob (2018)
16
17 revealed a significant impact of education on the development of cognitive abilities. The authors
18
19 reported beneficial effects of education on cognitive abilities of approximately 1 to 5 IQ points
20
21 for an additional year of education which persisted across the life span and were present on all
22
23 broad categories of cognitive ability studied. In addition, findings from longitudinal studies with
24
25 students in the German, three-track, secondary school-system indicate that the development of
26
27 students' general cognitive ability partly depends on the school track that the students attended
28
29 (Becker, Trautwein, Lüdtke, Köller, & Baumert, 2012; Guill, Lüdtke, & Köller, 2017).
30
31
32
33
34

35
36 Third, abilities differentiate and become more specific over time. Achievement in most
37
38 domains relies on the ability to learn, to understand new content, and to solve problems. This
39
40 general ability can be described as intelligence, conceptually defined as “a very general mental
41
42 capability that, among other things, involves the ability to reason, plan, solve problems, think
43
44 abstractly, comprehend complex ideas, learn quickly and learn from experience” (Gottfredson,
45
46 1997, p. 13). Different theoretical accounts assume that general ability is foundational for the
47
48 development of more specific abilities. In his theory of intelligence development, Garret (1946)
49
50 introduced the concept of ability differentiation with increasing age and ability, assuming a
51
52
53
54
55
56
57
58
59
60

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

16

1
2
3 structural change of intelligence from a single factor g (i.e., general intelligence) to various
4
5 specific factors.
6

7
8 Cattell's (1987) investment theory postulates that rather general, fluid abilities are
9
10 invested into the acquisition of crystallized abilities (e.g., specific knowledge or skills) by taking
11
12 advantage of learning opportunities. When the environment becomes more heterogeneous as life
13
14 unfolds, crystalized abilities, which are more strongly impacted by the environment, do so as
15
16 well; however, fluid abilities do not. This contrast, in turn, leads to a differentiation of abilities
17
18 and to the development of more specific abilities or specialized knowledge structures. Similar
19
20 ideas are expressed in Ackerman's (1996) intelligence-as-process, personality, interests, and
21
22 intelligence-as-knowledge (PPIK) theory. Empirical evidence does not support a general shift in
23
24 intelligence structure, but it supports the assumption of a differentiation of factors that refer to
25
26 more specific acquired contents and skills (*crystallized intelligence* or *intelligence-as-knowledge*;
27
28 Carroll, 1993; Schalke et al., 2013).
29
30
31

32
33 Fourth, ability development is intertwined with personality development. Theories of
34
35 intellectual development (e.g., Ackerman, 1996; Ziegler, Danay, Heene, Asendorpf, & Bühner,
36
37 2012) and theories that include the development of achievement (e.g., Marsh & Martin, 2011)
38
39 intertwine ability development with personality development. For example, in Ackerman's
40
41 (1996) PPIK theory, the transition from more innate perceptual and information-processing
42
43 components of intelligence (e.g., speed, reasoning, working-memory) to acquired knowledge and
44
45 skills is assumed to be influenced by personality traits and interests. A case in point are so-called
46
47 intellectual investment traits (e.g., need for cognition) that determine when, where, and how
48
49 people invest their time and effort in the development of their abilities and intellect (von Stumm
50
51 & Ackerman, 2013). Further, the development of abilities and interests is assumed to proceed
52
53
54
55
56
57
58
59
60

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

17

1
2
3 along mutually causal lines such that ability levels determine the probability of success in a
4 particular task domain, which in turn increases interest in this task, and personality and interests
5 determine the motivation for attempting the task.
6
7
8

9
10 The openness-fluid-crystallized-intelligence (OFCI) model (Ziegler et al., 2012) further
11 assumes positive reciprocal relations between the personality factor openness and fluid
12 intelligence (“intelligence-as-process” in PPIK). On the one hand, being open brings about more
13 learning opportunities, which positively affects the development of fluid intelligence
14 (“environmental enrichment” process); on the other hand, fluid intelligence, partly mediated by
15 its investment into building up knowledge and skills, positively affects openness because it
16 increases the likelihood of successfully managing tasks (“environmental success” process).
17
18 Similar positive reciprocal effects have been theoretically assumed and empirically supported for
19 the relation between academic achievement and academic self-concept (reciprocal-effects-model
20 REM; Marsh & Martin, 2011). That is, the development of ability factors and in particular of
21 more specific abilities or specialized knowledge and the development of nonability factors (e.g.,
22 self-concept, interests, investment traits) are related to each other within the process of talent
23 development that results in the development of specific ability-personality profiles (e.g., being a
24 “math person” with high abilities, investment, interest, and academic self-perceptions related to
25 math).
26
27
28
29
30
31
32
33
34
35
36
37
38
39
40
41
42
43

44 Fifth, ability-personality profiles inform talent development. A process of ability
45 differentiation that is intertwined with the development of non-ability factors (see above) leads to
46 the formation of ability-personality profiles that differ among persons (e.g., Ackerman, 1996).
47
48 These profiles comprise individual constellations of abilities, interests and values, motivational
49 variables, or self-concepts that inform further talent development over a wide range of
50
51
52
53
54
55
56
57
58
59
60

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

18

1
2
3 achievement levels including exceptional achievement (Ackerman & Heggestad, 1997; Snow,
4
5 1991). Although mean levels of achievement-related factors are useful for predicting the
6
7 achievement level of an individual, an individual's ability-personality profile is useful for
8
9 predicting domain selection and the domain in which the person achieves best (Coyle, Purcell,
10
11 Snyder, & Richmond, 2014; Coyle, Snyder, & Richmond, 2015; Dekhtyar, Weber, Helgertz, &
12
13 Herlitz, 2018; Lubinski, Webb, Morelock, & Benbow, 2001; Makel, Kell, Lubinski, Putallaz, &
14
15 Benbow, 2016; Park, Lubinski, & Benbow, 2007, 2008; Wang et al., 2013, 2017).

16
17
18
19 Of note, ability-related profiles seem to be more scattered in high-ability individuals
20
21 (Lohman, Gambrell, & Lakin, 2008). Spearman's (1927) law of diminishing returns (SLODR)
22
23 describes this phenomenon as a special case of ability differentiation: With increasing ability
24
25 level, correlations among different ability factors decrease. Stated differently, SLODR refers to
26
27 ability-dependent differences in loadings of the general intelligence factor g on more specific
28
29 ability factors (i.e., smaller g -loadings with increasing general ability level). A review
30
31 (Hartmann & Nyborg, 2004) as well as a recent meta-analysis (Blum & Holling, 2017) both
32
33 found significant support for the SLODR-hypothesis. Studies further indicate SLODR effects
34
35 not only in older but also in younger age groups (e.g., kindergarteners: Tucker-Drob, 2009; 6-18
36
37 year olds: Reynolds & Keith, 2007).
38
39
40
41

42
43 In sum, ability-personality profiles are important to understand domain choices or, more
44
45 generally, the process of specialization within talent development. Investment and success in a
46
47 domain reinforce identification with the domain (e.g., by self-concept formation) which, in turn,
48
49 enhances investment and success (Marsh & Martin, 2011). The formation of an identity as an
50
51 expert in a respective domain (e.g., being able to say "I am a psychologist" instead of "I study
52
53 psychology") supports self-efficacy which is needed for further investment, self-regulation
54
55
56
57
58
59
60

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

19

1
2
3 within the investment process, and creative productivity (Bledow, Rosing, & Frese, 2013). Thus,
4
5 there are positive reciprocal effects between ability-personality profiles and achievement. As
6
7 empirical evidence points to more differentiated ability profiles among high-ability individuals,
8
9 these profiles might be especially important for understanding talent development in these same
10
11 groups. In high-ability groups, an individual's ability-personality profile seems not only to be
12
13 predictive for the chosen domain but also for creative productivity within that domain (Lubinski,
14
15 2016). Further, ability-personality profiles might also predict the likelihood of being able to
16
17 move to a higher level of achievement. Usually, only current levels of achievement are used to
18
19 make this prediction, but future achievement is dependent on a host of other factors that reveals
20
21 little about the readiness of the individual for what is required at the next stage of talent
22
23 development. Research on ability-personality profiles in this context seems to be a promising
24
25 direction for understanding and supporting talent development.
26
27
28
29
30

31 There are several open questions regarding specialization. If talent development follows
32
33 a trajectory of increasing specialization as assumed in the TAD framework, then several
34
35 important questions arise. Is there an optimal point in time for focusing on one domain or
36
37 activity within that domain (e.g., is earlier specialization better than later specialization)? Should
38
39 a person choose a main activity and drop others to invest in that activity (a priori specialization)
40
41 or should a person choose one main activity from multiple activities the person has invested in (a
42
43 posteriori specialization)? Do answers to these questions vary for different activities within a
44
45 domain and among domains? Although the concept of deliberate practice suggests that early
46
47 specialization is beneficial for talent development (Ericsson, 2006; Ericsson, Krampe, & Tesch-
48
49 Roemer, 1993), research from the domain of sports suggests that in senior elite sports, highly
50
51 successful athletes were characterized by later specialization and greater amounts of organized
52
53
54
55
56
57
58
59
60

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

20

1
2
3 involvement in other sports than less successful athletes, although both groups did not differ on
4
5 the amount of sport-specific deliberate practice (Güllich, 2014, 2017, 2018).
6
7

8 Güllich (2018) used the *multiple sampling and functional matching hypotheses* to explain
9
10 ~~the~~ these findings: Rather than “putting all eggs in one basket” from the outset, more successful
11
12 athletes’ participation patterns implied that they opened various career options, furthered them
13
14 simultaneously over multiple years, and kept them open for a relatively long time. The election
15
16 of the main sport emerged from athletes’ own experiences of various sports and thereby
17
18 multiplied the probability of electing the sport of individual “best fit” (Güllich, 2018, p. 2262).
19
20 Moreover, experiences with other sports might have led to diversified learning experiences that
21
22 increased different skills and the process of motor learning in itself (*learning transfer as*
23
24 *preparation for future learning hypotheses*; Güllich, 2018). To conclude, for the domain of
25
26 sports and independent of the general amount of deliberate practice, later specialization seems to
27
28 be associated with higher adult performance compared to early specialization; comparable
29
30 research for other achievement domains is missing.
31
32
33
34

35 **Level-Dependent Predictors and Indicators**

36
37 The final two columns of Figure 3 address level-dependent predictors and indicators.
38
39 Like the megamodel, TAD understands talent development as a cumulative process in which the
40
41 relative importance of predictors varies over time or level of talent development (i.e., aptitude,
42
43 competence, expertise, transformational achievement). That is, some variables like general
44
45 cognitive ability or motivation can be important from early on and remain important throughout
46
47 the person’s development. Others, like social skills can gain in importance as the individual
48
49 transitions from being a novice student to become an advanced student or professional. Beyond
50
51 that, the TAD framework aims to describe which predictors and indicators should be assessed
52
53
54
55
56
57
58
59
60

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

21

empirically at various levels. These serve to identify *potential as an individual's constellation of psychological factors that indicate the likelihood of a positive development of achievement to the next level*. Accordingly, what defines potential can change with level, allowing for tracking progress in the talent domain.

The choice of appropriate psychological features to serve as predictors and indicators of talent development depends on the specific domain and developmental level (see section, “Application of the TAD Framework to Different Achievement Domains”). Psychological variables with predictive power for describing talent development at different levels include cognitive variables (e.g., intelligence, working memory, perceptual abilities, creativity), personality variables (e.g., openness and further investment traits, conscientiousness, emotional stability), motivational variables (e.g., achievement motivation, interests, values, self-concept), and psychosocial skills (e.g., resilience, empathy, receptiveness to feedback, a growth mindset) including self-regulatory skills (e.g., coping, goal setting, self-regulated learning; for overviews see Jarvin & Subotnik, 2010; Lipnevich et al., 2016; Ng et al., 2005; Schneider, 2000; Schneider & Preckel, 2017; Strenze, 2007).

Within the TAD framework, it is assumed that at the *aptitude* level, factors like general cognitive ability, openness, and achievement motivation are highly relevant for talent development indicated by ease and speed of learning and responsiveness to learning new content and skills. For acquiring *competence* in a given domain, more specific abilities related to that domain and its choice as well as successful learning become highly relevant; these include associated personality factors (e.g., investment traits, conscientiousness, or self-concepts) as well as interests and values (Ackerman, 1996; Holland, 1997). At the *expertise* level, learning abilities are no longer sufficient and need to be complemented by the intelligent application of

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

22

gained knowledge and skills, which requires more developed and advanced meta-cognitive skills. In most domains, persuasive strategies to sell one's expertise necessitate social competencies and a sensibility for opportunities (Sternberg & Lubart, 1991, 1992).

Finally, making a *transformational achievement* that moves a domain's boundaries entails keeping up investments at a high level, which requires persistent motivation and psychological strength, like the ability to cope with rejections and failures and the keep up faith in oneself (Jarvin & Subotnik, 2010). Moreover, it can become important to make one's work visible and to convince others, enhanced by a set of characteristics sometimes termed as "charisma." The concept of charisma is mainly discussed within theories of leadership (Dinh et al., 2014) and is associated with a transformational leadership style (Bass, 1990). The two sub-dimensions of transformational leadership, "idealized influence" and "inspirational motivation," can be combined under the designation of charisma (Phaneuf, Boudrias, Rousseau, & Brunelle, 2016).

The generic structure and specification of TAD as an empirical prediction model is very straightforward. For empirical investigations, one could use linear regression models or other predictive statistical models that accommodate non-linear relations, variance in change rates, multi-level structures, interactions, or moderators and mediators. The accuracy of an empirical TAD model can be expressed in terms of *R*-squared or some other measure of model fit. The more a set of predictors explains in the variance of an outcome measure, the better the prediction of a TAD model. Model predictions are likely to be more accurate for shorter time intervals and more fine-grained increases in achievement (represented by the breath of the arrows in Figure 3). Hence, choosing shorter time intervals can be beneficial for model construction and will require fewer changes to the assessment of psychological features and achievements in a given domain.

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

23

1
2
3 TAD suggests investigating predictors' validity within one level and between adjacent
4 levels rather than focus on long-term predictive validity. Models from the TAD framework
5 therefore do not rely on the assumption that individual psychological variables need to have
6 strong predictive power across long-term developmental spans (i.e., not relying on the
7 assumptions that a test taken at age 5 can predict high achievements at age 20 with sufficient
8 accuracy). Instead, achievement outcomes of a given developmental level, that is, indicators of
9 talent development within this level, are predicted primarily by psychological variables assessed
10 at the beginning of the same level. However, for successive levels, we assume a considerable
11 overlap in appropriate predictors and indicators. In addition, the relative importance of
12 predictors over time might differ. It is also important to note that within TAD the levels of talent
13 development are not defined in terms of chronological age, but in terms of positions on the
14 developmental trajectory (see also, Jarvin & Subotnik, 2010). Whether and how these levels
15 might be linked to critical time windows measured with respect to chronological age needs to be
16 determined in future research on domain-specific talent development.

22
23
24
25
26
27
28
29
30
31
32
33
34

35 To conclude this section, the TAD framework allows for a systematic comparison of
36 domains regarding psychological predictor variables. Some psychological variables will be
37 domain-specific but others can be powerful predictors that are common to more than one
38 domain. It is then an empirical question to identify significant predictors shared across domains.
39 The assessment of achievements, however, will be entirely dependent on the domain (e.g.,
40 mathematics, music, visual arts; see section "Application of the TAD Framework to Different
41 Achievement Domains") and needs to consider the developmental level. Table 1 offers a
42 summary of the main ideas of the TAD framework.

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

24

Environmental and Genetic Factors

In order to reduce complexity and facilitate the formulation of testable hypotheses deduced from the framework, TAD's primary focus is on person-related psychological variables. Nevertheless, talent development clearly hinges on multiple environmental and genetic factors.

Environmental Factors: The Role of Learning Opportunities and Instruction

Successful talent development at the aptitude level requires that a child has many opportunities for learning, trying out new things, and coming into engaging contact with different domains; also important are exercising the beginnings of deliberate practice and competent teachers (Jarvin & Subotnik, 2010; Subotnik et al., 2011). Further, students should have access to advanced content that typically becomes interesting at an older age. At the competence level, regular intense learning experiences within the child's zone of proximal development in a domain (Ericsson et al., 1993; Vygotsky, 1978) are essential. Learning conditions and settings are needed that allow meaningful learning (e.g., scaffolding, acceleration, enrichment, special schools or programs), acquiring strategies for independent learning, maintaining high levels of motivation, and finding a place within the learning setting where personal needs are fulfilled (e.g., finding friends, being accepted by teachers and classmates) (Hattie, 2009; Ryan & Deci, 2017).

In addition, many learners need support in overcoming certain social and societal hurdles and limitations (e.g., gender role stereotypes, social class) and in coping with possible experiences of feeling different (derived, for example, by separation from origin, family, ethnic group) experienced through educational and social advancement. Here, personal mentors in the broadest sense can take on a very important role (Subotnik & Jarvin, 2005). At higher levels of talent development, important environmental factors include the time and place for an intensive

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

25

1
2
3 study of the domain (Lee, 2016). These factors are related to the possibility of financial support
4
5 or to the compatibility of work and family life. Additional factors include exchange and
6
7 collaboration with a community of colleagues in the field (Subotnik & Jarvin, 2005).
8
9

Genetic Factors: The Role of Gene-Environment Interplay

10
11
12 As outlined in the preceding section, talent development is impacted by the environment
13
14 and the experiential effects related to it (e.g., opportunities, practice, instruction). These
15
16 experiential effects, in turn, dynamically interact with genetic factors and influence individual
17
18 (talent) development. Within this so-called gene-environment interplay, genetic effects moderate
19
20 experiential effects and the other way round which, over time, can lead to correlations between
21
22 specific genetic and experiential effects (Tucker-Drob, 2018). For instance, Mosing, Madison,
23
24 Pedersen, Kuja-Halkola, and Ullén (2014) investigated a large sample of Swedish twins and
25
26 found that, for the domain of music, the inclination to practice itself was substantially heritable
27
28 (40%–70%).
29
30
31

32
33 The dynamic processes related to this complex interplay can be illustrated with the
34
35 *Matthew effect* whereby initial differences magnify over time (e.g., “the bright get brighter”).
36
37 For example, children with higher fluid intelligence that is partly based on genetic factors (e.g.,
38
39 Knopik et al., 2007) are able to learn more successfully than less intelligent children, as higher
40
41 fluid intelligence predicts higher learning gains (e.g., Kaufman, DeYoung, Gray, Brown, &
42
43 Mackintosh, 2009; Wang, Ren, & Schweizer, 2017). This experience and the feedback related to
44
45 it can motivate more intelligent children to rely more on their cognitive abilities, to invest in their
46
47 learning, and to actively seek out or evoke situations in which their cognitive abilities are
48
49 stimulated. That is, interindividual differences of a genetically influenced trait⁴ can lead to
50
51 differences in learning gains and in the selection and evocation of environmental experiences
52
53
54
55
56
57
58
59
60

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

26

1
2
3 (i.e., experience-producing drives; Bouchard, 1997). Absolute pitch (Ruthsatz, 2014) or figure
4
5 drawing (Arden, Trzaskowski, Garfield, & Plomin, 2014) are further examples for traits with a
6
7 genetic underpinning that predict talent development in music and visual arts, respectively.

8
9
10 Thus, one's genetic makeup influences the experiences and activities that one seeks out, leading
11
12 to differential profiles of talent development by genotype (Tucker-Drob, 2018).
13

14
15 Preconditions for the selection and evocation of “fitting” environments are the
16
17 availability of and access to different options as well as resources to help shape environments.
18
19 With increasing age and knowledge, a person’s autonomy and resources usually increase to
20
21 select and evoke fitting environments (Scarr & McCartney, 1983), and, in better fitting
22
23 environments, genetic effects on talent development might even increase (Briley & Tucker-Drob,
24
25 2014). Stated differently, with increasing specialization or expertise, one might assume stronger
26
27 genetic effects for talent development. For example, in the domain of music, Hambrick and
28
29 Tucker-Drob (2015) found that genetic effects on music accomplishment were stronger among
30
31 adolescents who engaged in music practice as compared to adolescents who reported not
32
33 practicing; this finding suggests that genetic effects for skilled performance increased with
34
35 practice. Moreover, Vinkhuyzen, van der Sluis, Posthuma, and Boomsma (2009) analyzed data
36
37 from multiple achievement domains and found stronger genetic evidence for exceptional
38
39 achievement in a specific domain as compared to average achievement.
40
41
42
43

44
45 To conclude, genetic and environmental factors are of utmost importance for talent
46
47 development in different achievement domains. Their significance is recognized within the TAD
48
49 framework. However, to make the framework more parsimonious and open to empirical
50
51 investigation, genetic and environmental factors are not specified within the TAD framework
52
53 depiction (see Figure 3). Rather, their impact is assessed through the psychological lens of the
54
55
56
57
58
59
60

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

27

1
2
3 person (e.g., by individuals' report of their experience-producing drives or the opportunities
4 realized by the person). For models including environmental and genetic factors, see Gagné and
5 McPherson (2016) and Ullén et al. (2016).
6
7
8

Application of the TAD Framework to Different Achievement Domains

9
10
11 Here we present examples for uses of the TAD framework for model development in
12 three domains (i.e., mathematics, music, visual arts). Each example is structured in the same
13 way. First, the current state of talent development research in a domain is provided. Second, in
14 line with the TAD framework, the development of aptitude to transformational achievement is
15 described as a sequence, and empirical evidence is summarized that represents increasing
16 specialization and links level dependent predictors and indicators to the talent development in
17 that domain. Of note, TAD is a psychological framework aiming to allow predictions based on
18 the measurement of constructs. Therefore, the focus is on psychological predictors and
19 indicators for which rigorous measurement approaches are available. Third, literature gaps and
20 an outlook for future research are discussed.

Mathematics

35
36
37 Mathematics differs from most other achievement domains in that it is a core subject in
38 school and everyone is expected to attain a level of mathematical competence that enables them
39 to deal with typical demands and situations in adult life. This competence level, which is also
40 called numeracy or mathematical literacy, however, is not attained by a surprisingly large
41 proportion of the population. Approximately 5–7% of individuals suffer from a mathematical
42 learning disorder (dyscalculia; Butterworth, Varma, & Laurillard, 2011), and around 20% of
43 adults show mathematical difficulties imposing practical and occupational restrictions (Litster,
44
45
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

28

1
2
3 background, most psychological research has focused on atypical and typical mathematical
4
5 development covering the range from poor to average achievement. Within this area of research,
6
7 particular emphasis has been put on basic numerical abilities (e.g., understanding cardinality),
8
9 which are assumed to represent the cognitive foundation for acquiring higher-order mathematical
10
11 competencies.
12
13

14
15 Accordingly, most psychological models in this domain are restricted to the development
16
17 of these basic numerical abilities in preschool and their importance for the acquisition of
18
19 arithmetic skills in school (e.g., LeFevre et al., 2010; Siegler & Braithwaite, 2016). There are
20
21 few psychological models on mathematical talent development that go beyond mathematical
22
23 competencies taught in school or that specifically address high levels of achievement (e.g.,
24
25 expertise; but see Krutetskii, Teller, Kilpatrick, & Wirszup, 1976). Notably, only in mathematics
26
27 education, there are some frameworks describing different types of mathematical thinking (from
28
29 conceptual-embodied to axiomatic-formal; Tall, 2008) or levels of talent (e.g., Usiskin, 2000),
30
31 but they do not include specific assumptions on the psychological underpinnings and predictors
32
33 for different developmental levels. Therefore, the TAD framework has great potential to provide
34
35 an elaborate theoretical foundation for a comprehensive model of mathematical talent
36
37 development.
38
39
40
41

42
43 **Aptitude.** Valuable insights into the aptitude level of the TAD framework come from
44
45 research on basic numerical abilities and functions in atypically and typically developing
46
47 preschool children. This research has identified a set of early domain-specific abilities that are
48
49 associated with (in some cases predictive of) mathematical competencies acquired in school. For
50
51 instance, longitudinal research starting with kindergarten children and following them up until
52
53 the end of elementary school has demonstrated the importance of early awareness of numerical
54
55
56
57
58
59
60

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

29

1
2
3 quantities and their relationship for subsequent development of mathematical competencies (e.g.,
4
5
6 Krajewski & Schneider, 2009).

7
8 Research focusing on young school children has revealed that an adequate understanding
9
10 of the properties of numerical information is a critical prerequisite in mathematical development.
11
12 This comprises *cardinality* (i.e., numerical quantity) as well as *ordinality* (i.e., numerical
13
14 sequence) information. Cardinality processing is typically assessed by means of number
15
16 comparison tasks, in which children have to choose the larger of two numbers (presented either
17
18 as Arabic digits or dot patterns). Better performance on this task has been found to be associated
19
20 with higher mathematical competencies (Elliott, Feigenson, Halberda, & Libertus, 2019; Hawes,
21
22 Nosworthy, Archibald, & Ansari, 2019; Schneider et al., 2017), even in older populations with
23
24 higher achievement (Wang, Halberda, & Feigenson, 2017). The processing of ordinality
25
26 information has been tested frequently by asking participants whether number triplets are in
27
28 order (ascending or descending) or not. Likewise, the performance on this task has turned out to
29
30 be associated with school-taught mathematical competencies (Lyons, Vogel, & Ansari, 2016).
31
32 Recent research suggests that the importance of individual differences in both abilities changes
33
34 over development, with cardinality being more relevant at the beginning of primary school and
35
36 ordinality increasing its association with arithmetic skills later on (Lyons, Price, Vaessen,
37
38 Blomert, & Ansari, 2014; Vogel et al., 2017). Both cardinality and ordinality understanding
39
40 have been found to be impaired in children with dyscalculia (Butterworth et al., 2011; Morsanyi,
41
42 van Bers, O'Connor, & McCormack, 2018).
43
44
45
46
47
48

49 Second, considerable individual differences in domain-specific attentional processes,
50
51 which are also correlated with later mathematical competencies, have been observed. The most
52
53 prominent concept is *spontaneous focusing on numerosity* (SFON), which refers to the individual
54
55
56
57
58
59
60

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

30

1
2
3 tendency to spontaneously (i.e., in a self-initiated way) focus attention on numerical information
4
5 in the surroundings (Hannula & Lehtinen, 2005). Individual differences in this tendency were
6
7 originally assessed by a task in which children imitated actions of the experimenter that involved
8
9 quantity information (e.g., feeding a stuffed bird with a certain number of berries); however,
10
11 there is a wide range of different SFON measures. Cross-sectional as well as longitudinal studies
12
13 have revealed that the individual SFON tendency is related to later mathematical (in particular
14
15 arithmetic) competencies, over and above other basic numerical and domain-general abilities
16
17 (Rathé, Torbeyns, Hannula-Sormunen, De Smedt, & Verschaffel, 2016). In the past few years,
18
19 further spontaneous attentional tendencies have been proposed. School children's spontaneous
20
21 focusing on quantitative relations (SFOR) is related to later conceptual knowledge of fractions
22
23 and algebra (McMullen, Hannula-Sormunen, & Lehtinen, 2014). Kindergarteners' spontaneous
24
25 focusing on Arabic number symbols is associated with their numerical abilities (SFONS; Rathé,
26
27 Torbeyns, De Smedt, & Verschaffel, 2019).
28
29
30
31
32

33 Finally, there are two types of basic numerical tasks that are also associated with
34
35 mathematical competencies but which may not be purely domain-specific. The number line
36
37 estimation task requires children to locate a given number on an empty number line, thus also
38
39 requiring the processing of cardinality information (Siegler, 2016). Interestingly, the
40
41 performance on this task has been found to be more strongly related to different measures of
42
43 mathematical competencies than that in the number comparison task (Schneider et al., 2018).
44
45 However, it is an unresolved issue whether and to what extent this task draws on non-numerical
46
47 functions (e.g., spatial abilities, proportional reasoning) besides cardinality processing. A similar
48
49 limitation holds true for patterning tasks. Since patterns are considered central to mathematics
50
51 learning, tasks were developed to assess children's early patterning abilities (Wijns, Torbeyns,
52
53
54
55
56
57
58
59
60

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

31

1
2
3 De Smedt, & Verschaffel, 2019). In many of these, figural patterns are presented that need to be
4
5 continued by the children. Patterning task performance has been observed to be related to
6
7 mathematical competencies (Burgoyne, Malone, Lervag, & Hulme, 2019; Fyfe, Evans, Matz,
8
9 Hunt, & Alibali, 2017; MacKay & De Smedt, 2019), but it is unclear to what extent the involved
10
11 processes are specific to the domain of mathematics or rather reflective of fluid intelligence.
12
13

14
15 Thus, there are several early numerical abilities that are predictive of individual
16
17 differences in mathematical development in the lower-to-average performance range that can
18
19 therefore be considered as indicators of the potential to acquire mathematical competencies.
20
21 Practically all of them can be assessed quite easily using paper-and-pencil or computerized
22
23 measures. Many of these measures have been designed for detecting early numerical deficits in
24
25 children that may point to an atypical mathematical development. It is an open question,
26
27 however, whether high levels in these basic numerical abilities are indicative of high
28
29 achievement in mathematics beyond domain-general abilities.
30
31

32
33 **Competence.** An essential step in the development of mathematical competencies is the
34
35 acquisition of procedural knowledge of how to solve arithmetic problems and declarative
36
37 knowledge of arithmetic facts (e.g., the multiplication table). Although children with dyscalculia
38
39 have severe difficulties in acquiring this knowledge (Geary, 2013), children with high
40
41 mathematical potential can be expected to perform exceptionally well in arithmetic. Krutetskii
42
43 and colleagues (1976) observed that mathematically gifted children in primary school are
44
45 characterized by strong mathematical interest and propensity to calculate and compose arithmetic
46
47 problems. At higher grades (from the end of primary school on), Krutetskii et al. found gifted
48
49 children to differ from non-gifted children in several cognitive processes during mathematical
50
51 problem solving, including, for instance, the ability to grasp the formal structure of the problem,
52
53
54
55
56
57
58
59
60

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

32

1
2
3 to generalize and remember mathematical content, or to flexibly switch between mental
4
5 processes.
6

7
8 These and other processes were assumed by Krutetskii et al. (1976) to be closely
9
10 interrelated and to form a specific property of high mathematical potential: the *mathematical cast*
11
12 *of mind*. Mathematically gifted children “see the world ‘through mathematical eyes’” (Krutetskii
13
14 et al., 1976, p. 302); that is, they perceive and interpret the environment through the lens of
15
16 logical and mathematical categories. This cast of mind allows them to acquire mathematical
17
18 knowledge faster and attain higher levels of mathematical performance. In addition to this cast
19
20 of mind, creativity has been regarded as another important component of high mathematical
21
22 potential (Mann, 2006). At this level of talent development, students’ creativity is evaluated “in
23
24 relation to their previous experiences and to the performance of other students who have similar
25
26 educational histories” (Leikin & Lev, 2013, p. 185). McMullen et al. (2016) developed an
27
28 adaptive number knowledge task that draws on divergent thinking in arithmetic and, thus,
29
30 captures some part of mathematical creativity at this level.
31
32
33
34

35
36 Recent empirical research has largely focused on associations between mathematical
37
38 competencies and domain-general abilities. In sum, it has been found that higher competencies
39
40 are associated with higher information processing speed (Passolunghi & Lanfranchi, 2012),
41
42 larger short-term and working memory (Berg & McDonald, 2018; Peng, Namkung, Barnes, &
43
44 Sun, 2016), higher executive functions (Abreu-Mendoza, Chamorro, Garcia-Barrera, & Matute,
45
46 2018; Bull & Lee, 2014), enhanced logical reasoning abilities (Attridge & Inglis, 2013;
47
48 Morsanyi, Devine, Nobes, & Szucs, 2013), and better visuo-spatial abilities (Benbow & Minor,
49
50 1990; Frick, 2018). A review article by Myers, Carey and Szucs (2017) showed that these
51
52 general correlates of mathematical competencies can also be regarded as characteristics of
53
54
55
56
57
58
59
60

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

33

1
2
3 mathematically gifted individuals, even though the authors also noted that the current body of
4
5 evidence is too limited to draw strong conclusions on this issue.
6
7

8 Likewise, the relevance of domain-specific and domain-general abilities for the
9
10 prediction of later expertise development has been investigated only in very few studies. The
11
12 largest and most prominent research project in this context is the Study of Mathematically
13
14 Precocious Youth (SMPY; Lubinski & Benbow, 2006), which revealed that very high levels of
15
16 domain-general reasoning abilities in adolescents transform into exceptional academic
17
18 achievements in adulthood. For attainment in the mathematical domain, a specific ability profile
19
20 of high visuo-spatial and mathematical abilities turned out to be predictive (Wai, Lubinski, &
21
22 Benbow, 2009). Research findings on child prodigies in mathematics add to this body of
23
24 evidence by showing that these children score very highly on tests of general intelligence, visuo-
25
26 spatial abilities, and working memory (Ruthsatz, Ruthsatz-Stephens, & Ruthsatz, 2014).
27
28
29

30
31 Similar to other talent domains, psychosocial factors can be expected to loom large in the
32
33 acquisition of mathematical competencies. This holds particularly true for intrinsic motivation
34
35 and persistence (Subotnik, Pillmeyer, & Jarvin, 2009). The amount of empirical research on this
36
37 topic, however, is rather limited. In the review article by Myers et al. (2017), for instance, only
38
39 one study was reported in which mathematically gifted high school children were found to
40
41 exhibit a higher drive to succeed and a different pattern of interests (less interest in social,
42
43 interpersonal, or religious issues) compared to a control group (Kennedy & Walsh, 1965). In
44
45 sum, high mathematical competence at this developmental level should be reflected in high
46
47 levels of mathematical performance, specific problem-solving processes, and the production of
48
49 (relatively) original mathematical ideas. These domain-specific characteristics are
50
51
52
53

complemented by high levels of cognitive functioning (general and visuo-spatial intelligence) and motivational factors.

Expertise. According to traditional expertise research (Ericsson & Lehmann, 1996; Ericsson, Nandagopal, & Roring, 2005), mathematical expertise can be defined as consistently superior achievement, which is based on an extensive domain-specific knowledge base. This is built up over several years of intensive engagement, which requires extraordinary levels of intrinsic motivation and persistence. The current empirical evidence corroborates the requirement of high levels of motivation and persistence in order to intensively engage in this domain over a long time (Subotnik et al., 2009), and, very recently, some features of deliberate practice in mathematics have been explored (Lehtinen, Hannula-Sormunen, McMullen, & Gruber, 2017). In contrast to the talent domains, chess and music (Hambrick et al., 2014), however, there are no data yet on the importance of deliberate practice for expertise development in mathematics.

There seems to be consensus that mathematicians doing research can be considered as experts. They “ask questions, raise conjectures, discover new mathematical theorems, invent new mathematical concepts and tools and prove or refute previously raised but unproved mathematical conjectures” (Leikin, 2014). Previous studies suggest that they differ from non-mathematicians in both domain-general and domain-specific ability factors (for a recent overview, cf. Sella & Cohen Kadosh, 2018). First, expert mathematicians – similar to academics in other areas – display above-average levels of general intelligence (Wai, 2014). In addition, evidence from the SMPY and other studies indicates high levels of visuo-spatial abilities (Wai et al., 2009). Both findings hold true, however, only for research mathematicians but not for

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

35

1
2
3 calculation experts whose expertise lies in solving specific arithmetic problems (Butterworth,
4
5
6 2006).

7
8 Second, there is some research showing that mathematicians not only excel in high-level
9
10 mathematical tasks but also in more fundamental domain-specific processes. They outperformed
11
12 controls in computational estimation tasks by flexibly applying appropriate calculation strategies
13
14 (Dowker, 1992; Dowker, Flood, Griffiths, Harriss, & Hook, 1996; Obersteiner, Van Dooren, Van
15
16 Hoof, & Verschaffel, 2013), in a numerical agility task requiring flexible use of arithmetic
17
18 knowledge (Sella, Sader, Lollot, & Cohen Kadosh, 2016), and even in basic numerical tasks
19
20 drawing on cardinality processing (Castronovo & Göbel, 2012). In addition, their numerical
21
22 representations may be more abstract or spatially more flexible (Cipora et al., 2016). These
23
24 findings suggest that some fundamental numerical-mathematical processes may still be
25
26 particularly pronounced in expert mathematicians (see also, Amalric & Dehaene, 2016), which is
27
28 in line with the view that a mathematical cast of mind is a defining feature of achievement
29
30 potential in this domain. Finally, at the level of expertise, mathematical creativity becomes even
31
32 more important (Sriraman, 2008). Taken together, there is some research that reveals specific
33
34 cognitive profiles of expert mathematicians and that corroborates the importance of motivational
35
36 factors and creativity for reaching this developmental level.
37
38
39
40
41

42 **Transformational achievement.** At this level, individual mathematical expertise is
43
44 expressed in creative accomplishments that are considered as major or ground-breaking by the
45
46 scientific community. Psychological research on predictors for achieving this level is practically
47
48 non-existent. There are some qualitative and biographical studies involving eminent
49
50 mathematicians (e.g., Kolata, 1987; Simonton, 2004), which generally emphasize the
51
52 significance of the factors that turned out to be important for the previous level (in particular a
53
54
55
56
57
58
59
60

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

36

1
2
3 mathematical cast of mind, creativity, motivation and persistence). For instance, in the most
4
5 recent study of this kind, Mehta, Mishra, and Henriksen (2016) reviewed information on the four
6
7 2014 Fields Medal winners (the mathematicians' "Nobel Prize") and observed that all of them
8
9 reported to see mathematics everywhere, to be driven by creative avocations and aesthetic
10
11 aspirations, and to have a strong personal relationship to the domain.
12
13

14
15 **Gaps in the literature and a future research agenda.** Talent development in
16
17 mathematics appears to be a research field with numerous open questions in all four levels of the
18
19 TAD framework. At the aptitude level, the research focus needs to be extended from the lower-
20
21 to-average to the high performance range. In particular, it is unclear whether and to what extent
22
23 basic numerical abilities are indicators and predictors of high mathematical achievement. In the
24
25 development of mathematical competence, very little is known about the interplay of domain-
26
27 specific and domain-general factors for knowledge acquisition and performance. This
28
29 particularly applies for the relation of the mathematical cast of mind and intelligence as well as
30
31 psychosocial factors. Finally, in contrast to other expertise domains (e.g., music, chess), there is
32
33 a lack of research on the development of mathematical expertise and creative productivity.
34
35 Specifically, the importance of deliberate practice, domain-relevant experience, and psychosocial
36
37 skills is largely unknown. Further, there is a lack of research explaining specialization processes,
38
39 although there is evidence for the important role of ability-personality profiles for domain
40
41 selection and creative productivity in mathematics (Lubinski, 2016).
42
43
44
45

Music

46
47
48
49 Music is a domain that presents an almost paradoxical situation with regards to talent
50
51 development. On one hand, there are widely cited models of musical talent development (e.g.,
52
53 Davidson & Faulkner, 2013; Gagné, 2008; Kirnarskaya, 2009), there is widespread use of
54
55
56
57
58
59
60

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

37

1
2
3 teacher checklists for talent identification (Heller & Perleth, 2008; Ohio Department of
4
5 Education, 2009; Wisconsin Music Educators Association, 2009), and a long tradition of
6
7 perceptual tests that purport to measure musical talent (Bentley, 1966; Gordon, 1989; Seashore,
8
9 1919; Wing, 1968). On the other hand, musical talent models like the one suggested by Gagné
10
11 are not specified at a level that would allow empirical validation and there is a lack of convincing
12
13 evidence for any predictors of musical talent to have substantial predictive power for future
14
15 musical success (e.g., Howe, 1998; Manturzewska, 1990; Norton, Winner, Cronin, Lee, &
16
17 Schlaug, 2005).

18
19
20
21
22 A primary reason for the lack of an empirical model of musical talent development is the
23
24 scarcity of longitudinal studies that would provide the data necessary for specifying and testing
25
26 such models. Longitudinal studies are complex (Little, 2013) and expensive to run. Hence, the
27
28 few longitudinal studies in the music research literature do not make use of a comprehensive
29
30 quantitative assessment approach, but rely largely on qualitative research techniques (e.g.,
31
32 McPherson, Davidson, & Faulkner, 2012; Sloboda & Howe, 1991) or use only small samples
33
34 with a normal distribution of musical abilities, thereby lacking a specific focus on high
35
36 achievements or accelerated musical development (Gordon, 1975).

37
38
39
40 In addition, the decision to end formal musical training and to change career focus
41
42 despite a promising trajectory is common in musical careers (McPherson et al., 2012). It is
43
44 possible that limiting the definition of expertise and success to achievements as a musical
45
46 performer is too narrow, given the few opportunities to make a successful living as
47
48 instrumentalist compared to many other professional career options in music. This concern is
49
50 particularly salient in the realm of Western art music (Simonton, 1991), the primary subject of
51
52 academic studies of musical talent as well as talent identification checklists.

Another problem for the identification of quantitative indicators of musical talent is the often implicit assumption that quantitative features such as intelligence and working memory (Hansen, Wallentin, & Vuust, 2013), emotional engagement with music (Kirnarskaya & Winner, 1997), musical discrimination ability and musical memory (Gordon, 1986) assessed at an early age can serve as predictors for musical long-term development. However, the failure to identify long-term indicators of musical achievement so far seems to suggest that psychological variables assessed at an early age are predictive of the development of musical skills at early levels of development but have less predictive value for later developmental levels (or, alternatively, that suitable long-term predictors are still waiting to be discovered).

The TAD framework has several features that address these difficulties and, therefore, holds the promise to provide the necessary theoretical orientation for the development of an evidence-based model of musical talent that allows for rigorous empirical testing (~~including potentially falsification~~) as well as providing useful predictions for the musical trajectory of individuals. First, it focuses on measurable psychological constructs. Second, by breaking up the developmental trajectory into different levels, models from the TAD framework do not rely on the assumption that individual psychological variables need to have strong predictive power across long periods of musical development. Further, the four developmental levels of the TAD can be closely linked to Levels I to IV in Manturzewska's (1990) model of lifespan development of professional musicians that she developed from a large interview study with professional as well as artistically eminent musicians. Third, in line with the concept of musical sophistication (Müllensiefen, Gingras, Musil, & Stewart, 2014), the TAD framework does not prescribe only a single prototypical musical trajectory (e.g., as performer of Western art music), but also allows

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

39

1
2
3 for considering high musical achievements in other forms, including music composition or
4
5 production and in genres other than Western art music.
6

7
8 **Aptitude.** Within the TAD model of music development, high musical aptitude is defined
9
10 as general mental and physical potential to process, learn, and produce music at a high
11
12 achievement level in the future. Therefore, musical aptitude is developed before the start of any
13
14 systematic music instruction, that is, the first course of systematic music instruction received
15
16 from a teacher or the initial phase of self-directed music learning. Moreover, the term aptitude
17
18 describes the *potential* to go through the initial levels of systematic music learning. High
19
20 musical aptitude would be predictive of measureable high musical achievements after an initial
21
22 learning phase (i.e., after a few music/instrumental lessons or after a few sessions of self-directed
23
24 music learning). For musicians engaged in Western art music, the start of systematic music
25
26 instruction is often between 5 and 7 years. However, for many self-taught musicians within the
27
28 popular music genre, the start of systematic music learning can be much later, for example,
29
30 between 10 and 15 years. Consequently, the TAD framework avoids any general association of
31
32 windows of chronological time with developmental levels.
33
34
35
36

37
38 According to the literature, general psychological features that might be linked to high
39
40 musical aptitude and short-term musical achievements are intelligence (Schellenberg, 2011),
41
42 working memory (Vandervert, 2016), and basic motor skills relevant for the particular form of
43
44 instrumental learning. In addition, skills associated with high aptitude that are thought to be
45
46 music specific include sensory sensitivity and emotional understanding of music (Kirnarskaya &
47
48 Winner, 1997); cognitive auditory skills, including sequence memory and perceptual
49
50 discrimination skills (Gordon, 1986); singing ability (Howe, Davidson, Moore, & Sloboda,
51
52 1995); rhythmic skills (Kirnarskaya, 2009; Zuk, Andrade, Andrade, Gardiner, & Gaab, 2013);
53
54
55
56
57
58
59
60

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

40

1
2
3 and the development of musical imagination and spontaneous musical activity (Manturzewska,
4
5
6 1990).

7
8 To validate a predictive model, these general psychological as well as music-specific
9
10 variables should be assessed ideally before the first music lesson or first self-directed music
11
12 session. Subsequent achievement should be assessed after a period of several sessions.
13
14 Achievement can be determined through structured reports from multiple observers (e.g.,
15
16 instrumental teacher, class teacher, parents, peers) following the guidelines suggested by
17
18 Haroutounian (2000). In addition, the development of music perception abilities can also be
19
20 measured via an increase in tonal, rhythmic and harmonic abilities on standardized listening
21
22 tests. Musical achievements after this early music learning phase should reflect the ability to
23
24 benefit from instruction and feedback, the cognitive and sensory-motor mastery of basic musical
25
26 elements, the command of means of musical expression (i.e., dynamics and articulation), the
27
28 ability to combine mastered elements to more complex musical objects, and the ability to self-
29
30 learn and self-correct during music production to a certain degree. In sum, musical aptitude
31
32 according to the TAD framework comprises psychological factors that are beneficial to the first
33
34 stage of musical learning and permits the prediction of musical achievements after units of initial
35
36 instruction or self-directed teaching.
37
38
39
40
41

42 **Competence.** Musical competence describes the cumulative acquisition of skills
43
44 necessary for widening the musical repertoire of music as well as the range of expressive
45
46 scenarios and musical contexts that an individual can contribute to. For music performers,
47
48 developing competence includes the mastery of increasingly complex pieces and the ability to
49
50 perform in different settings (e.g., solo, together with other performers, or as part of an ensemble
51
52 or a band) and to change expressivity at will and independent from musical structure.
53
54
55
56
57
58
59
60

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

41

1
2
3 Competence also includes the cognitive and perceptual recognition and processing of complex
4 regularities in musical structure. In addition, the ability to make independent aesthetic and
5 creative decisions and execute these also ranks among the achievements at the competence level.
6
7 Depending on the genre of music, competence includes an understanding of harmony, rules for
8 the generation of melodic lines, complex rhythmical patterns, the links between emotional
9 expressivity and sound texture and dynamics, as well as the rules for the interaction of multiple
10 voices and instruments.
11
12
13
14
15
16
17
18

19 These achievements can be assessed through structured reports by multiple observers
20 (Haroutounian, 2000) and—depending on the ability to verbalize introspections of the music
21 learner—through self-report. The features frequently suggested as beneficial for high
22 achievement at the competence level are a growth mindset (Dweck, 2000; Müllensiefen,
23 Harrison, Caprini, & Fancourt, 2015); the ability to self-motivate, a positive musical self-concept
24 (Spychiger & Hechler, 2014); the integration of musicality into self-concepts (Müllensiefen et
25 al., 2015); motor skills (Kopiez & Lee, 2006); teachability; the ability to cope with failure; self-
26 motivation to learn (Jarvin & Subotnik, 2010); and the “rage to master,” a high level of intrinsic
27 motivation to perform exceptionally well in the domain (Winner, 1996).
28
29
30
31
32
33
34
35
36
37
38
39

40 The transition from aptitude to competence level is continuous and hence there is no clear
41 starting point for the competence level. However, most authors (Gembris, 2009; Maturzeswka,
42 1992) agree that time deliberately (and without external pressures) invested into musical learning
43 is an indicator. Hence, the beginning of the competence level could be defined as the point in
44 time where a substantial increase in the time dedicated to musical learning is discernible. Taken
45 together, the competence level is the stage where an individual masters increasingly complex
46 musical materials as well as broadening the musical repertoire and expressive scenarios to a
47
48
49
50
51
52
53
54
55
56
57
58
59
60

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

42

1
2
3 considerable degree. The increased competence is reflected in the cumulative acquisition of
4
5 necessary skills which goes in hand with a substantial increase in the time deliberately dedicated
6
7 to musical learning.
8
9

10 **Expertise.** With regards to musical development^{al}, expertise might be characterized by a
11
12 superior level of musical skills that is recognized by peers and allows an individual to act within
13
14 professional contexts. In the music domain, expertise can be indicated for example by regular
15
16 performances for larger audiences or the regular production of music or the engagement of
17
18 music-related activities for the benefit of an audience (producing, editing, writing about music,
19
20 teaching, selecting music for commercial situations). Achievements at the expertise level might
21
22 be measured by the number, frequency and complexity, quality, creativity and diversity of
23
24 performances, musical productions, or music-related products. Although number and frequency
25
26 of musical productions can be easily measured objectively, judging the complexity, quality,
27
28 creativity, and diversity will usually require some form of peer expert judgement.
29
30
31
32

33 The transition from the competence to the expertise level is also a continuous process and
34
35 marking the starting point of the expertise level for the assessment of psychological features is
36
37 difficult. But part of the expert status is the recognition that an individual's work reflects a
38
39 strong grasp of the domain such that the performer is capable of generating good solutions to
40
41 important domain problems (Subotnik et al., 2019). Therefore, an indicator of expertise can be
42
43 the marked increase in time invested in outward facing musical activities compared with private
44
45 musical engagement such as deliberate practice and exercising.
46
47
48

49 Features considered relevant for the development of musical expertise that should be
50
51 assessed at the beginning of the expert level include relative psychological stability, openness to
52
53 experience, conscientiousness, resilience, obsessiveness (Winner, 1996), rational deployment of
54
55
56
57
58
59
60

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

43

1
2
3 time as well as mental and monetary resources, and the ability for critical but constructive
4
5 judgement of one own's work (Sternberg, 1999). In summary, the level of musical expertise is
6
7 often characterized by the increasing amount of musical activity that is outward facing and
8
9 directed towards an audience. Musical experts are usually able to act within professional
10
11 contexts and to provide good solutions to difficult musical problems that are recognised by their
12
13 peers.
14
15

16
17 **Transformational achievement.** Musical achievements at the level of creative
18
19 productivity are characterized by the volume of professional artistic output, commercial success,
20
21 artistic recognition from expert judges and a wide audience, the influence on other musicians,
22
23 and the freedom to make aesthetic and creative choices at the highest level. Predictors for
24
25 achievements at this level include the ambiguous attribute, charisma, as well as other factors that
26
27 are only partially psychological (Jarvin & Subotnik, 2010). Chance and context can be equally
28
29 important factors for creative productivity, which include opportunities and events that are
30
31 outside an individual's control. Hence, statistical modelling of high musical achievements at this
32
33 level might not be feasible because of the large number of potential predictors and the difficulties
34
35 associated with their measurement.
36
37
38
39

40
41 In addition, the data available on individuals working in the musical domain at the
42
43 creative productivity level will be small. Therefore, qualitative research (Folkestad, 2004),
44
45 descriptive statistics (e.g., Simonton, 1977, 1996), retrospective self-reports (Krampe, 1994,
46
47 2006) or biographical studies (Manturzewska, 1992) might be more appropriate at this level.
48
49 Hence, creative productivity and sustained contributions to the musical world are hallmarks of
50
51 the highest level within the TAD framework. At this level, factors such as a chance, charisma,
52
53
54
55
56
57
58
59
60

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

44

1
2
3 and aesthetic choice might be factors that are at least equally responsible for achievements as are
4
5
6 psychological constructs.

7
8 **Gaps in the literature and future research agenda.** The descriptions of the four
9
10 developmental levels highlight the core principle of an empirical implementation of the TAD
11
12 model: Future musical achievements at the end of a developmental phase or broader
13
14 developmental level are predicted from the level of current musical achievements and from a set
15
16 of psychological features. Hence, the main task for the construction of an empirical test of the
17
18 TAD model is to define suitable assessment measures of musical achievement and sets of
19
20 psychological features that might have predictive power for specific levels and phases of musical
21
22 development. However, what suitable assessment measures and psychological features are
23
24 depends massively on the musical genre, the type of music education, and the age range of
25
26 participants observed. Therefore, assessment measures and psychological variables can only be
27
28 chosen within the context of specific study and not a priori and in a blanket way. Although the
29
30 degree of musical aptitude for initial music learning can be assessed in a large proportion of the
31
32 general population, fewer and fewer individuals will develop to obtain musical competence and
33
34 expertise; and only a tiny fraction will be able to make a transformational achievement to the
35
36 music world. Hence, suitable assessment will need to reflect this increasing specialization of the
37
38 population under study.
39
40
41
42
43

44
45 In any case, the most principled way of testing the TAD framework empirically is the
46
47 analysis of longitudinal data over a specific period (e.g., kindergarten time, primary school years
48
49 or adolescence) that allows for the comparisons of musical achievements at later time points with
50
51 achievements and psychological profiles at earlier points in time. The implementation of such a
52
53 study is a primary item on the future research agenda for the TAD model in music.
54
55
56
57
58
59
60

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

45

Visual Arts

Contemporary visual art is an ill-defined and varied domain, encompassing a wide range of styles, activities, and media—many with only a tenuous link to traditional modes of naturalistic depiction. This social reality greatly complicates ecologically valid considerations of talent development in visual art (especially at its more advanced levels), but its initial manifestations still tend to involve the activity of drawing and the progressive mastery of realism. That said, the research literature on talent development in visual art is thinner than in music or mathematics, but there are still some useful guideposts for measureable predictors and indicators of talent development.

Aptitude. In visual art, early forms of aptitude typically refer to realistic drawing performance, rather than evidence of creative expression. All normally developing children draw. Moreover, they evince a well-established progression of stages of childhood drawing (Kerlavage, 1998; Lowenfeld, 1947/1982; Luquet, 1927/2001). Children between 1 year and 3 years old scribble with no concern for representation. Between ages 3 and 4, they enter a *preschematic* stage, drawing more intentional shapes and lines and designating the marks as particular objects; the simple “tadpole” figure representing a person is emblematic of this stage. By 5 or 6, children reach a *schematic* stage, demonstrating more control over drawn shapes coupled with an assimilation of culturally prevalent schemas for representation, like depicting a house by a triangle atop a square. By 7 or 8, children start to be more critical of their own work, and by age 10 or so, without proper instruction and encouragement, many will stop drawing altogether.

As summarized by Winner and Drake (2013), aptitude for visual art is evident in several developmental qualities that are characteristic of precocious young artists. First, they learn very

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

46

1
2
3 rapidly in the domain, passing through the same sequence of stages as other children, but doing
4
5 so notably faster. Indeed, their depictions are typically advanced by at least several years beyond
6
7 their non-precocious counterparts. They may draw recognizable shapes and differentiate basic
8
9 body parts by age 2, use fluid contour to outline complex shapes, draw objects in noncanonical
10
11 orientations, add rich detail, and suggest depth by the full range of historically hard-won
12
13 techniques of Western artists: foreshortening, occlusion, size diminution, shading and modeling,
14
15 and linear perspective. Drawing prodigies also show a high level of intrinsic motivation to
16
17 perform exceptionally well (“a rage to master”) and thus work compulsively, needing no outside
18
19 encouragement. Precocious artists also make discoveries through self-teaching and they can do
20
21 things, like employ a complex but accurate fluid contour line beginning at any part of an object
22
23 or vividly recall something previously seen, that are *never* mastered by ordinary children. Even
24
25 by age 5, some prodigies are drawing at a level considerably more sophisticated than most
26
27
28
29
30
31 adults.

32
33 A more specific psychological basis of prodigious (or even well above-average)
34
35 childhood performance in drawing remains elusive, as few researchers have examined this issue
36
37 in detail. There is some empirical evidence that such children have a bias toward processing
38
39 local details (that is, being able to draw details without the distraction of the broader context;
40
41 Drake, Redash, Coleman, Haimson, & Winner, 2010; Drake & Winner, 2011). Several other
42
43 markers for precocious drawing skill have also been identified, including a higher-than-average
44
45 incidence of non-right-handedness (Mebert & Michel, 1980), linguistic deficits like dyslexia
46
47 (Gordon, 1983), and poor stereopsis (depth perception produced by the brain receiving input
48
49 from both eyes; Livingstone, Lafer-Sousa, & Conway, 2011). Also, adult artists often
50
51
52
53
54
55
56
57
58
59
60
anecdotally report having been intently involved with visually analyzing the world at young ages

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

47

(Schlewitt-Haynes, Earthman, & Burns, 2002), a visual analog, perhaps, of spontaneous focusing on patterns or numerosity among budding mathematicians. More broadly, Gardner (1973) speculated that young artists “may be characterized ... by greater sensitivity to sensory stimulation and to the works of others; usual capacity for awareness of the relationship between stimuli; heightened fluency of ideas; predisposition to an empathy of wide range; and keen and agile sensorimotor equipment” (p. 256).

This last set of possibilities highlights the complexities inherent in early artistic talent development. It also raises a common theme in identifying talent in achievement domains: the extent to which early aptitudes reflect domain-specific versus domain-general capacities. This question is a significant issue in visual art, because realistic drawing requires the artist to solve the same kinds of problems as the visual system does generally, with a concomitant need for flexibility in processing (Kozbelt & Ostrofsky, 2018). Relatedly, just as aspects of mathematical reasoning may overlap with broader visual-spatial ability, the same may be true of drawing, in that a broader comprehension of spatial relations or quantitative reasoning may be useful for (and in turn benefit from) other aspects of the activity of drawing. Finally, it remains unclear how any predictors that are useful for identifying artistic talent in young children may or may not continue to hold in later years, as additional competence and expertise accrue.

In sum, drawing talent often manifests itself very early. Because virtually all children draw, and the features of their depictions unfold in a predictable agewise sequence, precocious artists may be readily identified by their accelerated development, very high intrinsic motivation, and mastery of complex depictive techniques. Certain biological markers, including perceptual strengths like a bias toward local processing, have been tentatively identified as supporting prodigious artists’ abilities.

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

48

1
2
3 **Competence.** Although most children stop drawing regularly by age 10 or so, those who
4
5 have some talent often persist, and they continue to improve in their realistic depiction ability as
6
7 well as artistic originality. Much more empirical research has been conducted on differences
8
9 between artists and non-artists in this regime of talent development, which may be said to extend
10
11 to the age where a budding artist has made a career commitment to the domain, usually by
12
13 enrolling in post-secondary-level (that is, college) art training. In terms of education and career
14
15 development, many future artists pursue such training, though curricula vary widely across
16
17 different institutions and programs.
18
19
20

21
22 A major focus of this line of research has been on the constellation of perceptual
23
24 strengths that are associated with drawing skill. These mainly appear to involve top-down
25
26 attentional control and high-level object understanding and visual analysis. Specifically, artists
27
28 show perceptual advantages on tasks involving visual memory and mental rotation ability
29
30 (Perdreau & Cavanagh, 2015; Winner & Casey, 1992), object recognition (Kozbelt, 2001;
31
32 Kozhenikov, Blazhenkova, & Becker, 2010), dis-embedding complex figures (Chamberlain et
33
34 al., 2019; Kozbelt, 2001), enhanced efficiency in the perceptual processing of objects (Perdreau
35
36 & Cavanagh, 2014), more astute selection of important visual features (Kozbelt, Seidel,
37
38 ElBassiouny, Mark, & Owen, 2010; Ostrofsky, Kozbelt, & Seidel, 2012), and enhanced
39
40 flexibility in shifting attention between the global and local aspects of a stimulus (Chamberlain
41
42 & Wagemans, 2015; Perdreau & Cavanagh, 2013) or between different interpretations of a
43
44 bistable figure (Chamberlain et al., 2019). And although the evidence is not always consistent,
45
46 artists' advantages do not appear to extend to lower-level processes like perceptual grouping
47
48 (Ostrofsky, Kozbelt, & Kurylo, 2013), overcoming perceptual constancies (McManus, Loo,
49
50
51
52
53
54
55
56
57
58
59
60

4
5
6 visual illusions (Chamberlain & Wagemans, 2015).

7
8 Several studies (Chamberlain et al., 2019; Kozbelt, 2001) have found that artists'
9
10 perceptual advantages can justly be regarded as largely a subset of their drawing advantages.
11
12 This finding implies that perceptual advantages are developed mainly to the extent that they are
13
14 useful in drawing, in turn suggesting a developmental interplay between drawing and perception.
15
16 Very little longitudinal research has directly pursued this question, however, so the psychological
17
18 and perceptual dynamic of talent development, as visual artists develop competence in their
19
20 domain, remains mysterious. Beyond refining perceptual skill and gaining domain-specific skills
21
22 and knowledge, visual artists continue to develop a growing repertoire of techniques to describe
23
24 their understanding of themselves and their world, using art-making to navigate complex issues
25
26 of identity formation in adolescence, within their sociocultural context (Burton, 1981; Gude,
27
28
29
30
31 2007).

32
33 In sum, the development of artistic competence—as a talented child transitions into a
34
35 nascent professional artist—is accompanied by the development of greater artistic skill as well as
36
37 additional perceptual strengths, which have been examined in many empirical studies. Although
38
39 many of these skills are beginning to be understood, many questions about their longitudinal
40
41 development and relation to each artist's emerging creativity, style, and sense of self-identity
42
43 remain unanswered.
44

45
46
47 **Expertise.** The later levels of talent development in visual art are more elusive and
48
49 fraught than earlier levels, and much less research has attempted to disentangle their various
50
51 strands. The most well-established research traditions on talent and visual art, described
52
53 above—such as the typical stages of drawing development and precocious drawers' divergence
54
55
56
57
58
59
60

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

50

1
2
3 from it, or the nature of artists' perceptual advantages—may simply not be very relevant for
4
5 high-level artistic expertise or achievement in the contemporary world. Indeed, irrespective of
6
7 whether or not a post-secondary-level studio art program emphasizes realistic drawing skills,
8
9 other aspects of the activity of art-making appear to be very important in order for a budding
10
11 artist to “make it” as a professional. Undergraduate-level (BFA) or graduate-level (MFA)
12
13 training in visual art is not nearly as rigorous or uniform as in other aesthetic domains like music
14
15 or dance.
16
17

18
19 Moreover, the very process of art education, and its purported payoff for professional
20
21 advancement, is not well understood – witness the pessimistic title of James Elkins' (2001) book
22
23 on art schools, *Why Art Cannot Be Taught*. At the very least, as Sawyer (2006) noted, “even if
24
25 art schools don't teach one how to make art, we know that they can teach one how to talk like an
26
27 artist, how to write like an artist, and how to participate in the art world” (p. 188). In sum, an
28
29 ecologically valid characterization of artistic expertise, and its relation to earlier stages of talent
30
31 development described above, remains elusive—perhaps because in practice these levels are
32
33 more dissociated than in better-structured domains, with less predictability in who will
34
35 successfully manage the transition.
36
37

38
39 **Transformational achievement.** Regardless of attained competence or expertise, for a
40
41 person to maintain a status as a full-time professional artist in the modern world, many things
42
43 have to go right. Successful artists may show high levels of grit and other motivational factors
44
45 (Duckworth, 2016), but chance factors (see Simonton, 1999) and socio-cultural aspects of
46
47 creativity like gatekeeping (Csikszentmihalyi & Csikszentmihalyi, 1988; Subotnik et al., 2019)
48
49 are probably important in inducing a very high attrition rate, whereby few individuals are
50
51 ultimately able to support themselves entirely by a career creating visual art.
52
53
54
55
56
57
58
59
60

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

51

1
2
3 Tied to this reality, the concept of creativity as inherent to visual arts practice is very
4 important—indeed, visual art remains probably *the* paradigmatic domain for creativity, generally
5 (Sawyer, 2006). Research on the creative process in artists suggests that some modes of
6 creativity are more likely to lead to career success. For instance, a greater willingness to engage
7 in problem finding behavior, in not settling for easy solutions, and continuing to
8 opportunistically revise an emerging artwork (Getzels & Csikszentmihalyi, 1976; see also Dudek
9 & Côté, 1994; Kozbelt, 2008) was associated with success in the art world some years later (see
10 also Csikszentmihalyi & Getzels, 1989). Other scholars have suggested multiple paths to real-
11 world creative success, including not only exploratory problem-finding but also high-level
12 conceptual innovation (Galenson, 2001, 2006), or artists banding together into collective
13 movements (Accominotti, 2009), or sensitivity to the predominant socio-cultural milieu (Sawyer,
14 2006), which may fluctuate between valuing different modes of creativity.

15
16
17 In sum, as with higher-level, artistic education, professional, real-world creativity in
18 visual art remains a woefully understudied phenomenon, particularly from the standpoint of
19 talent development and what could be done to help guide promising artists toward success. Any
20 advances in our knowledge are likely to remain provisional, given the ill-defined and shifting
21 nature of the domain itself.

22
23
24 **Gaps in the literature and future research agenda.** As the preceding discussion
25 suggests, many themes and aspects of the trajectory of talent development in visual arts are not
26 well understood. Basic research to fill in these lacunae would be useful, but even then the nature
27 of the domain itself is a complicating factor for our understanding. Among the issues to be
28 addressed are the following. For aptitude, it would be useful to develop a richer sense of
29 perceptual antecedents and associates of outstanding early drawing skill, as well as a more
30
31
32
33
34
35
36
37
38
39
40
41

47
48
49
50
51
52
53
54
55
56
57
58
59
60

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

52

1
2
3 inclusive sense of early artistry, not limited to realism. Better understanding competence would
4
5 result from continued research on perceptual correlates of outstanding drawing skill, including
6
7 more longitudinal studies and research on neural substrates, motoric aspects of drawing, and
8
9 their relation to expressions of artistic creativity. For expertise, a far more complete
10
11 understanding of the nature and utility of college-level training in art would be beneficial.
12
13

14
15 Analogously, for transformational achievement, a richer characterization of the necessary
16
17 skill set for navigating the professional art world, including aspects like the nature of
18
19 gatekeeping, would be tremendously informative. For both expertise and transformational
20
21 achievement, a more detailed sense of how perceptual advantages and other factors that are
22
23 demonstrably important at the aptitude and competence levels continue to influence later levels
24
25 (or not) would be helpful. At all levels, the particular, highly domain-specific and idiosyncratic
26
27 aspects of creative expertise in visual art are not well understood – particularly how they emerge
28
29 from the fairly domain-general constellation of competencies characteristic of younger artists.
30
31

Conclusion

32
33
34
35 The TAD framework provides a general talent development framework applicable to a
36
37 wide range of achievement domains. The overarching aim of this framework is to support
38
39 empirical research on talent development in different domains by (a) offering a common basis of
40
41 concepts and definitions that can be used across several domains, (b) focusing on measurable
42
43 psychological constructs and their meaning at different levels of talent development, and (c)
44
45 integrating the internal processes that lead to becoming interested and successful in a domain.
46
47 Compared to its springboard, the megamodel by Subotnik et al. (2011), the TAD framework puts
48
49 a stronger focus on the role of internal psychological variables and processes that are related to
50
51 talent development. Further, whereas the megamodel emerged from a descriptive synthesis of
52
53
54
55
56
57
58
59
60

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

53

1
2
3 the literature, the TAD framework can be used to guide such a synthesis. In a first step, for each
4 domain, empirical evidence for increasing specialization and level-dependent predictors and
5 indicators of talent development can be reviewed to build a domain-specific, talent development
6 model. In a next step, open questions and research gaps can be identified according to the
7 model. And finally, specific predictions about talent development in a specific domain can be
8 derived from the model and empirically tested.
9

10
11
12
13
14
15
16
17 We provided examples for the application of the TAD framework to the domains of
18 mathematics, music, and visual arts. The empirical evidence clearly shows that the process of
19 talent development varies by domain, even though several cross-domain similarities could be
20 identified. For example, talent development starts early in all three domains (i.e., in the pre-
21 school years). At the *aptitude* level, all domains list general cognitive abilities (i.e., working
22 memory, reasoning or fluid intelligence) as predictors of aptitude and precocity, engagement,
23 and the ease or speed of learning as indicators. Further, domain-specific, attentional information
24 processing seems to be relevant in all domains (e.g., a spontaneous focusing on domain-relevant
25 stimuli like numerosity, rhythm, or visual details) as well as the motivation to proceed with
26 domain-specific tasks and challenges. Differences among domains can be found, for example, in
27 the role of motor abilities which are highly relevant for drawing and playing an instrument but
28 which are less important for mathematics. Another example refers to self-teaching. Although it
29 seems to be a predictor of talent development in the domains of music and the visual arts, its role
30 is unclear for the domain of mathematics.
31
32
33
34
35
36
37
38
39
40
41
42
43
44
45
46
47
48

49 At the *competence* level, findings from all three domains suggest the developmental
50 interplay between the person and the demands and features of a domain suggested by the TAD
51 framework. That is, although general cognitive ability still represents a predictor of talent
52
53
54
55
56
57
58
59
60

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

54

1
2
3 development, domain-specific, cognitive skills that in part result from engagement in a domain
4 gain importance (e.g., procedural and declarative knowledge about arithmetics, musical
5 structure, or visual perspectives). Further, all three domains list creativity and mental flexibility
6 as predictors of talent development. In addition, motivational variables like intrinsic motivation
7 and interest are still relevant, and personality variables such as conscientiousness become even
8 more relevant for talent development in all three domains as they support learning and
9 engagement. Overall, talent development at the competence level shows many similarities
10 across domains: although contents differ, learning and skill acquisition, creativity, and
11 motivation are central in all domains.
12
13
14
15
16
17
18
19
20
21
22
23

24 Findings for the *expertise* level are scarce in all three domains, which points to common
25 research gaps regarding, for example, the relative importance of general as compared to more
26 specific cognitive abilities, the relevance of indicators of talent development at the competence
27 level for high achievement at the expertise level, or specificities of ability-personality profiles of
28 experts in different domains. The same applies to the level of *transformational achievement*.
29 Although case studies emphasize factors like creativity, persistence, or psychological strength,
30 there is an overall lack of research on the development of expertise and transformational
31 achievement during later periods.
32
33
34
35
36
37
38
39
40
41

42 These research gaps in all three domains further reveal the need for longitudinal studies
43 that illustrate developmental changes in all these domains. In addition, there is a lack of
44 assessment instruments suited to capture talent development in sub-fields of a domain (e.g., in
45 the domain of music, for music composition, arrangement, selection, production, communication
46 etc.). Finally, with increasing levels of talent development, the number of persons decreases
47 while predictors of talent development might become more idiosyncratic (Simonton, 1999).
48
49
50
51
52
53
54
55
56
57
58
59
60

TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

55

1
2
3 Hence, statistical modelling of high achievements at this level might not be feasible, but more
4
5 retrospective (interview) studies, qualitative research, or quantitative single-case research
6
7 designs might be more appropriate at this level.
8
9

10 Overall, the review provided for the three domains indicates numerous research gaps and
11
12 open questions that should be addressed in future research. The TAD framework identifies many
13
14 of these open questions and has the potential to answer some of them by bringing together the
15
16 knowledge base from different domains, by structuring it according to the four levels of talent
17
18 development, by comparing predictors of talent development within and across levels or
19
20 domains, and by formulating common research questions that should be addressed in future
21
22 studies.

While taking a psychological perspective, we acknowledge the importance of contributions from other disciplines like philosophy, sociology, history, or economics for understanding achievement and its development. We are aware of the need to discuss achievement and its development from multiple perspectives and we would be happy if the current work would stimulate such a discussion.

²Worrell, Subotnik, and Olszewski-Kubilius (2018) give the following definition: Eminence is the title reserved for individuals with fully developed talents who are extremely gifted in a domain relative to other highly gifted producers and performers in that domain. This relative superiority is acknowledged by the most knowledgeable members of the domain, and is typically related to a contribution or sustained contributions that have had, or will have, a lasting and memorable impact on the domain (p. 248).

³*Achievement domain* refers to a domain that has its own quality and evaluative criteria, its own curricula, knowledge, and skills, and expected learning outcomes of the targeted curriculum or course of study (i.e., curriculum goals, objectives, or indicators).

⁴Of note, the extent to which variation in a trait is influenced by genetic factors, on the one hand, and the extent to which that trait is modifiable, on the other, are orthogonal considerations. That is, the extent to which variation in a trait is influenced by genetic factors does not tell anything about the extent to which that trait is modifiable.

Running head: TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

Table 1

Summary of the Main Assumptions and Research Implications of the Talent Development in Achievement Domains (TAD) Framework

The TAD Framework: Summary and Implications

Summary: The TAD framework ...

- is a general talent development framework
- can be used for constructing domain-specific talent development models as it offers a common set of concepts and definitions that can be used across several domains
- originates from the talent development Megamodel (Subotnik, Olszewski-Kubilius, & Worrell, 2011):
 - It describes the talent development process at four successive levels (i.e., aptitude, competence, expertise, and transformational achievement).
 - It follows the notion of a trajectory in talent development moving from general abilities to specific skills and competencies.
 - It conceptualizes talent development as dependent on a multiplicity of factors whose relative importance can vary with level of talent development.
- has a primary *psychological focus* on (measurable) person-related variables (while acknowledging environmental and genetic factors)
- focuses on internal processes that lead to interest and success in a domain:

Ability differentiation: General abilities are invested into the acquisition of specific knowledge or skills by taking advantage of learning opportunities leading to the development of more specific abilities or specialized knowledge structures.

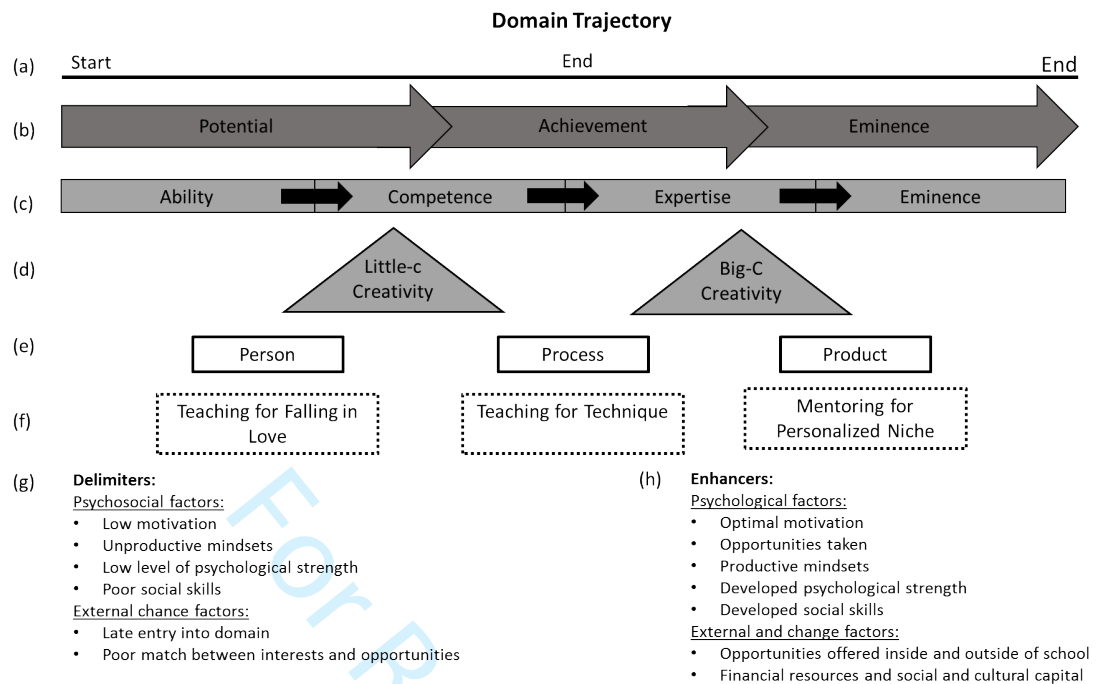

Interplay of ability development and personality development: Ability and personality factors develop along mutually causal lines within the process of talent development that results in specific ability-personality profiles.

Profiles inform talent development: Ability-personality profiles are important to understand the process of specialization within talent development. Investment and success in a domain reinforce identification with the domain that, in turn, enhances investment and success.
- suggests predictors and indicators of talent development at the four different levels that can be used to identify achievement potential and to track progress in an achievement domain

Implications: The TAD framework ...

- can be used to empirically identify significant predictors of talent development that differ/are comparable across different achievement domains
- suggests investigating the validity of predictors of talent development within one level and between adjacent levels more than focusing on long-term predictive validity
- defines levels of talent development in terms of positions on the developmental trajectory; it remains an open question whether and how these levels might be linked to critical time windows or age
- suggests investigating ability-personality profiles as predictors of specialization and as indicators of the readiness of an individual for what is required at the next level of talent development
- identifies open questions and research gaps (e.g., regarding the process of specialization)

Running head: TALENT DEVELOPMENT IN ACHIEVEMENT DOMAINS

**Legend**

- (a) Domains have developmental trajectories with different start, peak, and end times.
- (b) Giftedness in a domain is evaluated in relationship to others;
- (c) initially in terms of potential, later by demonstrated achievement, and finally, in adulthood, by eminence. The talent-development process involves several transitions whereby abilities are developed into competencies, competencies into expertise, and expertise into eminence.
- (d) Transitions are distinguished by levels of creativity, beginning initially with “little-c” creativity (independent thinking, entertaining different perspectives, creation of projects and products that are novel when compared to those of peers), and ultimately the “big-C” creativity required for eminence.
- (e) These transitions involve shifting emphasis from “person” (creative approach and attitude) to “process” (acquiring process skills and mind sets) “product” (creation of intellectual, aesthetic, or practical products or performances).
- (f) Each stage in the talent-development process is also characterized by different strategies and goals of instruction – initially to engage young people in a topic or domain (“falling in love”), then helping the individual to develop the needed skills, knowledge and values (“teaching for technique”), and finally, helping the talented individual develop their own unique niche, style method, or area of application (“mentoring for personalized niche”).
- (g) Movement from ability to eminence can be delimited by factors such as low motivation, mind sets that prevent coping with setbacks or thwart resiliency, less-than-optimal learning opportunities, or chance events.
- (h) Progress can be enhanced, maintained, or accelerated by the availability of educational opportunities including out-of-school enrichment and mentoring, psychological and social support from significant individuals, and social capital.
